## Spectral analysis of very hot H -deficient [WCE]-type central stars of planetary nebulae

## Graziela R. Kellern

Colaborators: Luciand Bianchi² and Weller J. Maciel

1/IAG/Universidade de São Paulo
2 The Johns Hopkinsuniversity
his presentation is organized as follows:

- Introduction
- Central Stars of Planetary Nebulae
- Stellar Winds
- Evolutionary Phase
- Model Grid
- The CMFGEN Code
- [WC] and PG1159 Grid
- Spectral Analysis
- NGC 6905, NGC 5189, NGC 2867.

Pb 6, and Sand 3

## Introduction

$\diamond$ They are Hot - $T_{*}$ between $20-200$ kK
Low Mass - $\mathrm{M}_{*}$ around $0.6 \mathrm{M}_{\odot}$
Surrounded by a Planetary Nebula

$\diamond$ Present Stellar Winds - Radiativelly Driven

## - Stellar Wind

 are continuous processes

## Beta velocity law:

$$
\vee_{\infty} \equiv \text { Terminal Velocity }
$$

Mass-loss rate: MEstarn

- Evolutionary Phase

- Evolutionary Phase

- Evolutionary Phase

## - Evolutionary Phase

## Some famous classes of $\underline{\mathrm{H} \text {-deficient CSPNe are: }}$

[WC] - Spectra similar to massive Wolf-Rayet stars;
-Strong carbon and helium emission Lines;
Are divided into early ([WCE]) and late type ([WCL]) objects.
PG1159 - Occupy the region at the top of the WD cooling track;

- Show absorption lines of highly ionized He, C, O;

Show UV wind lines much weaker than the ones seen in [WC] stars;
[WC]-PG1159 - Are believed to be transition objects between the two other classes.

## - Evolutionary Phase

Figure 3. Comparison between Pop.I Wolf-Rayet stars and central stars with late-type WC spectra. Wavelengths in angstrom.
Hamann 1996 Ap\&SS 238, 31

## - Evolutionary Phase [WC] X PG1159

C IV $\lambda \lambda 1548.2,1550.8 \AA$ line

Figure 6. Central stars of Wolf-Rayet type in the $\lg g-\lg T_{*}$-diagram. [WCL], [WCE] and [WC]PG 1159 subtypes are represented by squares, triangles and circles, respectively. Shaded diamonds indicate "normal" PG 1159 stars without strong mass-loss (after Dreizler et al. 1995). The tracks for post-AGB evolution taken from Schönberner (1983) or Wood \& Faulkner (1986) (labels: mass in $M_{\odot}$ ) and are only shown for rough comparison; they are not really adequate for the considered objects, as they predict normal surface abundances.

## AGB $\rightarrow[\mathrm{WCL}] \rightarrow[\mathrm{WCE}] \rightarrow[\mathrm{WC}]-\mathrm{PG} 1159 \rightarrow \mathrm{PG} 1159 \rightarrow$ WD

Hamann 1996 Ap\&SS 238, 31

## Support for this overall scenario comes from

1)Abundance patterns;
2)Proximity in evolutionary tracks;
3)post-AGB stars have been observed to re-expand and re-join the AGB, and afterwards, become a hot H -deficient CSPNe;
4)The nebulae around H -rich and [WC] and PG1159 stars are very similar and late thermal pulses happen randomly to about $20 \%$ of all post-AGB stars.

Many open questions lead to claims that the born again scenario may not be the only one forming these stars and invoking complicated close binary scenarios.
1)[WC] PN should always be too large for the position of the star on the HR diagram in comparison with a normal CS, but it is not so.
2) Recent estimates say more than $30 \%$ of CS are H -poor, while born again scenario predict at most $25 \%$.
3)Weird abundance H -poor ejecta in objects thought to have suffered a born again scenario (oxygen-neon-magnesium Novae).
4)Frequency of the [WC] central stars in different environments;
5)Too many [WCL] central stars relative to the [WCE] and PG1159 stars.
6)Different C/He mass ratios between [WCE] and [WCL] stars

## In this work, we:

Keller et al. 2011, MNRAS, 418, 705 :
Calculated a grid of models proper to the analysis of H poor CSPNe, covering Far-UV, UV, optical, and IR.
$\Delta$ Made the grids available on-line at
http://dolomiti.pha.jhu.edu/planetarynebulae.html
$\Delta$ Performed a differential analysis of the grid models to determine the best line diagnostics of stellar parameters.

Keller et al. 2014, MNRAS, 442, 1379:
©Used these results to perform a uniform and systematic analysis of UV and far-UV spectra of 5 [WCE] central stars.

## Model Grids

- Non-LTE; $\sqrt{ }$
- Expanding atmosphere;
- Line blanketing; $\sqrt{ }$
- Wind clumping; $\sqrt{ }$
$\checkmark$ Does not solve the dynamical $\boldsymbol{X}$ equations of the wind.

It requires the mass-loss rate and the velocity law to be supplied. In this work: with $\beta=1$;

* The mass-loss rate is a free parameter.
[WC] grid $\rightarrow 199$ models
PG1159 grid $\rightarrow 160$ models
Models vary in $L, T$, logg, $d M / d t$, and $V_{\infty}$.

Tracks: Miller Bertolami and Althaus (2006)

## Differential Analysis of Grid Models

We performed a differential study, showing the predicted impact of parameter variation on strengths and shapes of line profiles.

We determined the best line diagnostics of $\mathrm{dM} / \mathrm{dt}$ and $\mathrm{T}_{*}$.

# Spectral Analyses

# - Targets: FUSE range 

## Far Ultraviolet Spectroscopic Explorer - $(905-1187 \AA$ ) - resol. $\sim 0.06 \AA$

Observed

Synthetic

Figure 1. Left panel: FUSE spectra of the [WCE] CSPNe NGC 6905, NGC 5189, Pb 6 and NGC 2867. The numerous narrow absorptions are due to interstellar $\mathrm{H}_{2}$, which affects the blue edge of the Ne VII P-Cygni profile. Right panel: sample synthetic spectra from our model grid, calculated for different values of stellar temperature and two different mass-loss rates (in units of $\mathrm{M}_{\odot} \mathrm{yr}^{-1}$ ). All models shown adopt $v_{\infty}=2500 \mathrm{~km} \mathrm{~s}^{-1}$ and models of the same temperature adopt the same stellar radius. The observed and synthetic spectra shown were convolved with a Gaussian of $0.2 \AA$ FWHM for clarity.

t.w. $=$ this work; KH1997a=Koesterke and Hamann (1997a); KH1997b=Koesterke and Hamann (1997b); M2007=Marcolino et al. (2007b), BH1982=Barlow and Hummer (1982)
${ }^{a}$ Values obtained assuming $\log L / L_{\odot}=3.84$.
${ }^{b}$ Not constrained. Value assumed on the grid models was kept.
${ }^{c}$ Distances from Table 1.

## This Work x Literature: Abundances

## This Work x Literature: Abundances

Figure 14. The abundance intervals of PG1159, [WC]-PG1159 and [WC] stars (as found from the literature) are compared to the values determined in this work.

## Evolutionary Tracks

Figure 13. HR diagram with evolutionary tracks from Miller Bertolami and Althaus (2006). The open circles correspond to the sample objects. Sand 3 was omitted from it, because, to the best of our knowledge, there is no measurement of its distance in the literature.

## Conclusions

## Concluding...

We analyzed UV spectra from 5 of the hottest known [WCE]-type CSPNe using our grid of synthetic spectra, calculated with CMFGEN.
$\diamond$ Grids available at

## http://dolomiti.pha.jhu.edu/planetarynebulae.html http://www.astro.iag.usp.br/~graziela/GRIDWEB/front.html

We found line blanketing of $\mathrm{Ni}, \mathrm{Co}, \mathrm{Mg}$, and Na to improve the fit of the OV lines in all objects analyzed.
$\checkmark$ We revised up the temperatures for NGC 5189, NGC2867 and Pb 6.
We revised up the values of N abundances.
$\checkmark$ We constrained Ne mass fractions for the first time in [WCE] stars.
C:He mass ratios found by us span a wide range of values: $0.42<$ $\mathrm{C}: \mathrm{He}<1.96$.
